1. What is meningococcal disease?
Meningitis is caused by many kinds of germs. Meningococcal disease is caused by a bacteria (germ) called *Neisseria meningitidis*. This germ can be found in the upper respiratory tract (the body parts that help you breathe, like the nose, throat, and lungs). One out of every ten people will carry this bacteria in their nose, throat, and lungs without getting sick.

2. How does meningococcal disease spread?
The germ can spread from one person to another when there’s direct contact with saliva (spit), mucus, or air droplets that come out while coughing or sneezing. Close contact (like kissing) or living in the same household or sharing utensils (forks and knives), food, or drinks, can also spread germs.

3. What are the signs of meningococcal disease?
If you have several of these symptoms, immediately seek medical attention.
- High fever
- Stiff neck
- Rash
- Confusion
- Bad headache
- Nausea and vomiting
- Low blood pressure
- Muscle pain all over the body

4. How is meningococcal disease treated?
This kind of meningitis can be cured if treated early with antibiotics (medicine that kills bacteria).

5. How can you prevent the spread of meningococcal disease?
- Don’t share items that may spread germs through saliva, like utensils, food, drinks, lip balm or cigarettes.
- Wash your hands often with warm, soapy water for at least 20 seconds.
- Use your elbow or a tissue to cover your nose and mouth when you cough or sneeze.
- Don’t share drinks, food or utensils and limit contact with people who are sick.
- Talk to your doctor about vaccination if you think you have a higher chance of getting sick. If you’ve had recent close contact with a person that’s just had this kind of meningitis immediately contact your health care provider to get preventative medication.
- Vaccination is recommended for college students who live in dorms, workers in medical labs, people that are less able to fight off disease, and children and teens ages 11-12 with a second vaccine at 16 years old.
